Metoclopramide

This sheet talks about exposure to metoclopramide in a pregnancy and while breastfeeding. This information should not take the place of medical care and advice from your healthcare provider.

**What is metoclopramide?**

Metoclopramide is a medication that has been used to treat gastrointestinal motility issues, for nausea and vomiting caused by surgical operations, chemotherapy, or pregnancy, and to help with lactation. This medication has been sold under band names such as Reglan®, Maxolon® or Metozolv ODT®.

**Can taking metoclopramide made it harder for me to get pregnant?**

There have been some reports of menstrual problems and galactorrhea (milk production that is not related to breastfeeding) among women who have taken metoclopramide. Women who have these side effects might have a harder time becoming pregnant. However, studies have not suggested that metoclopramide would affect fertility (a person's ability to get pregnant).

**I have been taking metoclopramide and just found out I am pregnant. Should I stop?**

You should speak with your healthcare provider before making changes in this medication. If you are experiencing nausea and vomiting or gastrointestinal problems that are affecting your ability to function, speak with your healthcare provider about which medication would be best for you and your baby. For more information on nausea and vomiting in pregnancy, please see the MotherToBaby fact sheet on Nausea and Vomiting in Pregnancy at https://mothertobaby.org/fact-sheets/nausea-vomiting-pregnancy-nvp/pdf/.

**Can metoclopramide increase the chance for a miscarriage?**

Miscarriage can occur in any pregnancy. A small number of studies did not find an increased chance for miscarriage among women taking metoclopramide.

**Can taking metoclopramide during pregnancy cause birth defects?**

In every pregnancy, a woman starts out with a 3-5% chance of having a baby with a birth defect. This is called her background risk. Current information does not suggest an increased chance for birth defects when metoclopramide is taken early in pregnancy.

**Can taking metoclopramide during pregnancy cause other pregnancy complications?**

For the woman, maybe. There are case reports of women who developed severe side effects while taking metoclopramide during pregnancy which required them to be admitted to a hospital for treatment. In these reports, 2 women developed movement disorders (known as tardive dyskinesia) and 2 other women developed intermittent porphyria (a condition that affects the body’s ability to make red blood cells) which led to psychiatric conditions. All reports showed that these women got well with treatment and went on to have healthy newborns. These reports do not tell us how often this may occur during pregnancy and more studies are needed. If you are taking metoclopramide tell your healthcare provider about any changes in your mood or any movement disorders such as lip smacking, jerky eye movements, or jerky limb movements.

**Can I breastfeed while taking metoclopramide?**

Most likely. There is limited information on the use of metoclopramide during breastfeeding. Metoclopramide can cross into the breast milk. While most reports have not listed any side effects in the nursing infants, it has not been well studied. If your baby was to experience side effects, it would most likely be stomach discomfort and gas. If you are worried about any symptoms the baby has, contact the child’s healthcare provider. Metoclopramide use while breastfeeding might increase your chance for post-partum depression. Any changes in your mood should be reported to your healthcare provider.

**Is it true that metoclopramide can increase the amount of milk that I make?**
There are some small studies that looked at whether metoclopramide increases or causes milk production. One study found that metoclopramide use could slightly increase the amount of milk produced while a similar study found that it did not increase milk production. If you are having trouble with milk production, working with a lactation consultant may be the most helpful in increasing your breastmilk production. Be sure to talk to your health care provider about all of your breastfeeding questions.

**What if the father of the baby takes metoclopramide?**

There is no evidence that suggests that a man’s metoclopramide use would cause any problems during his partner’s pregnancy. In general, medications that the father takes do not increase risk to a pregnancy. For more information, please see the MotherToBaby fact sheet on Paternal Exposures at [https://mothertobaby.org/fact-sheets/paternal-exposures-pregnancy/pdf/](https://mothertobaby.org/fact-sheets/paternal-exposures-pregnancy/pdf/).
