Tramadol

This sheet is about exposure to tramadol in pregnancy and while breastfeeding. This information should not take the place of medical care and advice from your healthcare provider.

**What is tramadol?**

Tramadol is a narcotic prescribed to treat pain. It is in a group of medications called opioids. Ultram®, Ryzolt®, and Conzip® are all brand names for tramadol. Some forms of tramadol can also contain other medications, such as acetaminophen. An example is Ultracet®. For more information on acetaminophen, please see the MotherToBaby fact sheet at https://mothertobaby.org/fact-sheets/acetaminophen-pregnancy/.

**I just found out that I am pregnant. Should I stop taking tramadol?**

Sometimes when people find out they are pregnant, they think about changing how they take their medication, or stopping their medication altogether. However, it is important to talk with your healthcare providers before making any changes to how you take this medication. Your healthcare providers can talk with you about the benefits of treating your condition and the risks of untreated illness during pregnancy.

If you have been taking tramadol regularly or have a dependency (also called opioid use disorder), you should not just stop suddenly (also called “cold turkey”). Stopping an opioid medication suddenly could cause you to go into withdrawal. It is not known if or how withdrawal might affect a pregnancy. It is suggested that any reduction in tramadol be done slowly, and under the direction of your healthcare provider.

**I am taking tramadol, but I would like to stop taking it before becoming pregnant. How long does the drug stay in my body?**

People eliminate medication at different rates. In healthy adults, it takes up to 3 days, on average, for most of the tramadol to be gone from the body.

**I take tramadol. Can it make it harder for me to get pregnant?**

Studies have not been done to see if taking tramadol can make it harder to get pregnant.

**Does taking tramadol increase the chance of miscarriage?**

Miscarriage can occur in any pregnancy. Studies have not been done to see if taking tramadol increases the chance for miscarriage.

**Does taking tramadol increase the chance of birth defects?**

Every pregnancy starts out with a 3-5% chance of having a birth defect. This is called the background risk. Based on the studies reviewed, it is not known if tramadol increases the chance for birth defects above the background risk. One study found no increase in birth defects with tramadol use in the first trimester. Another study found an increase in the chance of birth defects, including small increases in heart defects and clubfoot. This study did not consider why the person who was pregnant was taking tramadol. It is not known if tramadol was the cause of the birth defects or if they were due to other factors such as the medical condition being treated.

Some studies that have looked at opioids as a group suggest that opioids in general might be associated with birth defects. However, studies have not found a specific pattern of birth defects caused by opioids. Based on these studies, if there is an increased chance for birth defects with opioid use in pregnancy, it is likely to be small.

**Does taking tramadol in pregnancy increase the chance of other pregnancy-related problems?**

Based on the studies reviewed, it is not known if tramadol can cause other pregnancy-related problems, such as preterm delivery (birth before week 37) or low birth weight (weighing less than 5 pounds, 8 ounces [2500 grams] at birth). One study did not find an increased chance for preterm delivery with tramadol use.

Studies involving people who often use some opioids during their pregnancy have found an increased chance for adverse outcomes including poor growth of the baby, stillbirth, preterm delivery, and the need for C-section. This is
more commonly reported in those who are taking a drug like heroin or who are using prescribed pain medications in
greater amounts or for longer than recommended by their healthcare provider. Use of an opioid close to the time of
delivery can result in withdrawal symptoms in the baby (see the section of this fact sheet on Neonatal Abstinence
Syndrome).

Will my baby have withdrawal (Neonatal Abstinence Syndrome) if I continue to take tramadol?

Studies have reported a chance of neonatal abstinence syndrome (NAS) with tramadol and some of the other opioid
medications. NAS is the term used to describe withdrawal symptoms in newborns from medication(s) that a person
takes during pregnancy. In the reports of NAS after tramadol use, doses of 200mg to 800mg were taken daily
throughout pregnancy. NAS symptoms began within the first week of life and included irritability, vomiting, stiff
muscles, and a fast heart rate. Because information is limited, it is not known if the chance of NAS is higher or lower
with tramadol than with other, better studied opioids.

For any opioid, symptoms can include difficulty breathing, extreme drowsiness (sleepiness), poor feeding, irritability,
sweating, tremors, vomiting and diarrhea. Most often, symptoms of NAS appear two days after birth and may last more
than two weeks. Most babies can be successfully treated for withdrawal while in the hospital. The chance that NAS will
occur depends on the length of time and/or the dose of opioid taken during pregnancy. If you use or have used opioids,
it is important that your baby’s healthcare providers know to check for symptoms of NAS, so your newborn gets the
best possible care.

Does taking tramadol in pregnancy affect future behavior or learning for the child?

Based on the studies reviewed, it is not known if tramadol increases the chance for behavior or learning issues. Some
studies on opioids as a general group have found more problems with learning and behavior in children exposed to
opioids for a long period of time during pregnancy. It is hard to tell if this is due to the medication exposure or other
factors that may increase the chances of these problems.

What if I have an opioid use disorder?

Studies find that people who are pregnant and take opioids in higher doses or for longer than recommended by their
healthcare providers (i.e. misuse or “abuse” opioids) have an increased chance for pregnancy problems. These include
poor growth of the baby, stillbirth, preterm delivery, and the need for C-section.

Tramadol and breastfeeding:

Speak to your healthcare provider about your pain and medications that may be used while you are breastfeeding.
Tramadol passes into breast milk in low levels. Babies might have problems with the amounts of tramadol in the breast
milk. Talk with your healthcare provider or a MotherToBaby specialist about your specific medication, as information on
breastfeeding might change based on your specific situation such as the age of your baby, the dose of medication, and
other factors. A study of 75 newborns exposed to tramadol through breastmilk found no extra problems compared to
other opioid medications that the person who was breastfeeding took after delivery.

The United States Food and Drug Administration (FDA) recommends that tramadol not be used during breastfeeding
due to concerns that the medication could build up to high levels in the baby’s system and cause problems, such as
trouble breathing or not waking to feed.

Use of some opioids in breastfeeding might cause babies to be very sleepy and have trouble latching on. Some opioids
can cause trouble with breathing. If you are using any opioid, talk to your healthcare provider about how to use the
least amount for the shortest time and how to monitor (watch) your baby for any signs of concern. Contact the baby’s
healthcare provider immediately if your baby has any problems such as increased sleepiness (more than usual),
trouble feeding, trouble breathing, or limpness. Be sure to talk to your healthcare provider about all your breastfeeding
questions.

If a male takes tramadol, could it affect fertility (ability to get partner pregnant) or increase the chance
of birth defects?

Use or misuse of opioids in general has been shown to lower fertility in males. Studies have not been done to see if a
male’s use of tramadol could increase the chance of birth defects above the background risk. In general, exposures
that fathers or sperm donors have are unlikely to increase the risks to a pregnancy. For more information, please see
the MotherToBaby fact sheet Paternal Exposures at
